Quick Response Code:

ABSTRACT

Objective: Atypical squamous cells of undetermined significance cytology (ASC-US) is a challenging and equivocal diagnosis for pathologists in cervical Pap smears. The data on ASC-US cervical cytology in Bahrain are deficient. This study reviewed and identified the reporting rates, high-risk human papillomavirus (HPV) testing results, histopathologic follow-up findings, and the cytologic progression of patients diagnosed with ASC-US in Bahrain.

Material and Methods: A retrospective chart review was conducted on the medical records of 23,888 women who had Pap smear test results between January 2019 and March 2022 at the main referral tertiary hospital in Bahrain to identify the ASC-US cases. High-risk HPV (hrHPV) genotype was identified, and the histopathological results of the cervical biopsy was recorded. In addition, cytologic follow-up Pap smear tests conducted within 1 year of ASC-US diagnosis were tracked to monitor the progression or regression of ASC-US.

Results: In this study, 259 out of 23,888 women reported to have ASC-US cytology results with a reporting rate of 1.1%. The mean age of the ASC-US cases was 43 ± 11.6. Thirty percent of the ASC-US cases tested positive for hrHPV, and they were predominantly infected with the other hrHPV genotype (75%). When the histopathological changes of the cervix were analyzed, 82.1% had normal histopathologic findings. However, low-grade cervical intraepithelial neoplasia-1 was reported in 2 cases (7.1%), and high-grade cervical lesions (cervical intraepithelial neoplasia-2 and higher) were reported in 3 cases (10.7%). Regarding the cytologic follow-up, most of the ASC-US cases were negative for intraepithelial lesion or malignancy (NILM) (73.8%) or had persistent ASC-US (17.9%). The remaining minority of cases progressed into either low-grade squamous intraepithelial lesions (6%) or high-grade squamous intraepithelial lesions (2.4%). There was a statistically significant and relatively strong association between the cytology follow-up findings and the hrHPV test results ($\chi^2 [2] = 8.869, P < 0.012, \text{Cramer's } V = 0.417$).

Conclusion: This is the first and largest study to characterize the ASC-US cytology cases in Bahrain. The reporting rates of ASC-US fell within the worldwide reported range. Although most of the ASC-US cases regressed into NILM, ASC-US showed progression into more advanced cervical cytologic diagnoses or contributed to the malignant transformation of cervical tissue, especially in the presence of hrHPV infection which was positive in 30% of the ASC-US cases. This emphasizes the role of cotesting (combination of hrHPV genotyping and Pap smear test) and the importance of colposcopic evaluation of those women with cytologic follow-up tests at 1 year of diagnosis. Implementing these recommendations in the cervical cancer screening practice in Bahrain will help in having a better management plan for women diagnosed with ASC-US cervical cytology.

Keywords: Atypical squamous cells of undetermined significance, Human papillomavirus, Cervical cytology, Cervical cancer, Cervical histopathology

INTRODUCTION

Atypical squamous cells of undetermined significance cytology (ASC-US) is a challenging and equivocal diagnosis for pathologists in cervical Pap smears. According to the 2014 Bethesda system for reporting cervical cytology, cervical epithelial abnormalities are categorized into squamous cell and glandular cell abnormalities each of which has several types.^[1] The squamous cell abnormalities are subcategorized into atypical squamous cells (of undetermined significance [ASC-US] and cannot exclude high-grade squamous intraepithelial lesions [ASC-H]), low-grade squamous intraepithelial lesion (LSIL), high-grade squamous intraepithelial lesion (HSIL), and squamous cell carcinoma.^[1] The atypical squamous cell subtype is the most prevalent of all abnormal cervical cytology interpretations, and ASC-US specifically comprises more than 90% of all squamous epithelial cell cervical smear cytology results.^[1] ASC-US refers to “changes that are suggestive of LSIL, but which are insufficient for a definitive interpretation as such.”^[1] The criteria for the diagnosis of ASC-US are the presence of mature squamous and squamous metaplastic cells with a high nuclear-to-cytoplasmic ratio and nuclear changes including hyperchromasia, chromatin clumping, irregularity, smudging, and/or multinucleation.^[1] The reporting rates of ASC-US among all cervical cytology results range between 2% and 10.9% in different regions of the world.^[2-5]

Human papillomavirus (HPV) is a well-established risk factor for cervical cancer. Twelve oncogenic types of HPV are classified as high-risk HPV (hrHPV), including types 16, 18, 31, 33, 35, 39, 45, 52, 56, 58, and 59.^[6] Cervical cancer is the eighth most common type of cancer among women in Bahrain, with an age-standardized incidence rate of 3.92/100,000 women/year.^[7] A relatively high proportion of women diagnosed with ASC-US are positive for hrHPV, which is reported to be 19–48.7%.^[3,4,8,9] ASC-US cytologic changes may increase the risk of developing high-grade cervical lesions, including cervical intraepithelial neoplasia-2 (CIN-2) and carcinomas, particularly in patients who tested positive for hrHPV.^[2,3,5,8] The current practice of cervical cancer screening in the primary health care and the gynecology departments of the secondary care hospitals in Bahrain is following the guidelines of the cervical cancer screening of the American Cancer Society.^[10]

The data on ASC-US cervical cytology in Bahrain are deficient. This study reviewed and identified the reporting rates, hrHPV testing results, the histopathologic follow-up findings, along with the cytologic progression of patients diagnosed with ASC-US in the main referral tertiary hospital in Bahrain, and the only center for the analysis of Pap smear samples received from all primary care health centers and the gynecology department, Salmaniya Medical Complex. The findings of this study have major implications for defining clinical and prognostic metrics of cervical cancer screening and therapeutic strategies in Bahrain.

MATERIAL AND METHODS

Study design

A retrospective chart review was conducted on the medical records of patients at Salmaniya Medical Complex, available at the National Health Information System (I-SEHA). The cytopathology reports for all Pap smears performed between January 2019 and March 2022 were reviewed to identify cases diagnosed with ASC-US. All women diagnosed with ASC-US cervical cytology in the study period were included in the study and no exclusion criteria were applied. Data on the demographic characteristics and the types of hrHPV identified were recorded. Histopathological results of cervical biopsy, endocervical curettage, or loop electrosurgical excision procedure/cone biopsy performed within 6 months of the Pap test were included in the study and were correlated with the cytology findings. Biopsy specimens were stained with hematoxylin and eosin. In addition, the specimens were stained with Ki-67 and P16 immunohistochemical stains. Biopsy results were categorized into three groups: (1) negative, (2) low-grade cervical lesion, cervical intraepithelial neoplasia-1 (CIN-1), and (3) high-grade cervical lesion (CIN-2 and higher). Follow-up Pap smear reports within 1 year of diagnosis were tracked to monitor the progression or regression of the cervical cytology changes.

Cytologic examination of the Pap smears

Cervical Pap smears were collected in liquid fixative vials (BD SurePath™ liquid-based Pap test, Becton Dickinson, Franklin Lakes, New Jersey, USA). The slide preparation and staining were done using an automated system (BD PrepStain™ System, Becton Dickinson, Franklin Lakes, New Jersey, USA). Microscopic examinations and reporting were performed by qualified pathologists according to the 2014 Bethesda System.^[11]

High-risk HPV detection

The detection of hrHPV was performed using the Xpert™ HPV assay (Cepheid, Sunnyvale, California, USA), and the real-time polymerase chain reaction (PCR) was run in the GeneXpert system (Cepheid, Sunnyvale, California, USA). 14 hrHPV types were tested, and the results were reported as negative or positive for HPV16, HPV18/45, or other hrHPV (31,33,35,52,58,51,59,39,56,66,68).

Statistics

The age was reported as mean age \pm standard deviation and median age. The ASC-US reporting rates were calculated from the total Pap smear tests conducted in the study period. To compare the histopathologic findings or the cytologic follow-up findings with the hrHPV test results, a Chi-square test of independence was conducted. $P \leq 0.05$

was considered statistically significant. The strength of the relationship between those categorical variables was tested using Cramer's V.^[11] The statistical analysis was done using IBM Statistical Package for the Social Sciences Statistics version 29.0.1.0.

RESULTS

ASC-US reporting rates

During the 39-month retrospective study period, a total of 23,888 Pap smear tests were analyzed. From which 259 women were diagnosed with ASC-US, with an overall reporting rate of 1.1%. The reporting rate of ASC-US showed an increasing trend over the years where it doubled from 0.8% in 2019 to 1.6% in 2021. While in the first 3 months of 2022, only the reporting rate was 1% [Table 1].

Demographic features of the study population

The mean age of the 259 women residing in Bahrain who were diagnosed with ASC-US is 43 ± 11.6. Based on the age group, 55.6% of the participants were between 30 and 49 years old, 31.7% were 50 years old and above, and 12.7% were <30 years old. Most of the ASC-US cases were Bahrainis (81.5%) [Table 2].

The hrHPV rates among ASC-US

Among the ASC-US cases, 160 (61.8%) had hrHPV genotyping test results. The overall hrHPV positivity rate among them was 30%. Women aged 30-49 had the highest hrHPV rate (62.5%), and those aged <30-years-old had the lowest rate (16.7%) [Table 3]. Most of the ASC-US cases tested positive for the other hrHPV (75%). This was followed by HPV 16 (12.5%) and HPV 18/45 (4.2%). The remaining 8.4% of the hrHPV-positive ASC-US cases had coinfection with at least two types of the virus (HPV 16 and 18/45 [2.1%], HPV 16, and other hrHPV [4.2%], and HPV 16, HPV 18/45, and other hrHPV [2.1%]) [Table 3].

Table 1: ASC-US reporting rates per year (2019–2022).

Year	Number of total Pap smears	Number of ASC-US	Reporting rate of ASC-US (%)
2019	8581	67	0.8
2020	3674	49	1.3
2021	4485	74	1.6
2022 (Jan-March)	7148	69	1.0
Total	23,888	259	1.1

ASC-US: Atypical squamous cells of undetermined significance

Histopathologic findings of women diagnosed with ASC-US

Of 259 women with ASC-US cytology, only 28 (10.8%) underwent histopathologic examination within 6 months of diagnosis. Among them, 82.1% had normal histopathologic findings. However, high-grade cervical lesions (CIN-2 and higher) were reported in three cases (10.7%), and CIN-1 was reported in two cases (7.1%) [Table 4]. Two out of three cases diagnosed with CIN-2 and higher were positive for the other hrHPV, and the third case was not tested for hrHPV. Regarding the two cases diagnosed with CIN-1, one of them tested positive for hrHPV (HPV 18/45 genotype) and the other one tested negative [Table 4]. A Chi-square test of independence was conducted between the histopathologic findings of the ASC-US cases and the hrHPV test results. There was not a statistically significant association between the histopathologic findings of the ASC-US cases and the hrHPV test results, $\chi^2(1) = 0.787, P < 0.375$ [Table 4]. A representative example of a cervical biopsy specimen diagnosed with cervical intraepithelial neoplasia-3 is shown in Figure 1.

Cytology follow-up findings of women diagnosed with ASC-US

Overall, 32.4% of patients had a repeated Pap smear test within 1 year of ASC-US diagnosis. The majority of the ASC-US cases were negative for intraepithelial lesion or malignancy (NILM) (73.8%) or had persistent ASC-US (17.9%). The remaining minority of cases progressed into either LSIL (6%) or HSIL (2.4%) [Table 5]. Representative examples of ASC-US, LSIL, and HSIL cervical cytology are shown in Figure 2. It was observed that 25 out of 34 (73.5%) cases that regressed into NILM and seven out of 13 (53.8%) cases that had persistent ASC-US were hrHPV negative. All

three cases that progressed into LSIL and the one case that progressed into HSIL (with an HPV test done) were positive for hrHPV [Table 5]. A Chi-square test of independence was conducted between the cytology follow-up findings of ASC-US cases and the hrHPV test results. There was a statistically significant association between the cytology follow-up findings and the hrHPV test results, $\chi^2(2) = 8.869$, $P < 0.012$ [Table 5]. The association was relatively strong (Cramer's V = 0.417).^[11]

HPV 16 and HPV 18/45 and other hrHPV	1 (2.1)

ASC-US: Atypical squamous cells of undetermined significance, hrHPV: high-risk human papillomavirus, HPV: Human papillomavirus

To elaborate further, the two ASC-US cases that progressed into HSIL were for 35-years-old and 50-years-old patients. The Pap smear was repeated for them at 8 months and 3 months, respectively, after the first ASC-US diagnosis where HSIL cytologic changes were observed. Both cases regressed into NILM on further follow-up within 1-2.5 years.

DISCUSSION

In this study, a total of 23,888 Pap smear tests were interpreted, of which 1.1% were diagnosed with ASC-US cervical cytology. Although there was an increase in the reporting rate over the years in the study period, it is still falling within the benchmark range reported by the CAP survey.^[12] Higher rates were reported in the Gulf Cooperation Council countries (GCC) overall (10.9%) and in the United Arab Emirates (5.3%).^[4,5] In China, the reporting rates were 3.8% and 4.2% in two different studies.^[2,3]

HrHPV positivity among women with ASC-US varies among different populations and is based on the technique used to detect HPV. The proportion of ASC-US patients who tested positive for hrHPV is 34.89-48.7% in the Chinese population, 30.3-40.1% in the United States, 21% in the GCC countries, and 19% in Kuwait.^[3,4,8,9] In a large-scale study, the mean percentage of hrHPV positivity for ASC-US was 43.74% among 69 laboratories in the United States.^[13] Those figures are comparable to the findings of this study, where the hrHPV positivity among ASC-US is 30%. In line with the results of two studies conducted in the GCC, the most identified genotype of hrHPV in ASC-US cases was the other hrHPV.^[4,9] This can be partially explained by the fact that the most prevalent hrHPV type reported in Bahrain is the other hrHPV.^[14] On the contrary, hrHPV types 16 and/or 18 were commonly identified genotypes in ASC-US patients in China.^[2,3]

In our study, three out of 28 women diagnosed with ASC-US (10.7%) developed high-grade cervical lesions, and two

$$\chi^2(2) = 8.869, P\text{-value} < 0.012, \text{cramer's } V=0.417$$

ASC-US: Atypical squamous cells of undetermined significance, HPV: Human papillomavirus, hrHPV: High-risk human papillomavirus, NILM: Negative for intraepithelial lesion or malignancy, LSIL: Low-grade squamous intraepithelial lesion, HSIL: High-grade squamous intraepithelial lesion

of them tested positive for other hrHPV. The association between ASC-US and the presence of high-grade cervical lesions have been studied previously. In one study, the histopathologic follow-up findings of ASC-US cases revealed that 7.87% of ASC-US cases had high-grade cervical lesions.^[2] Those high-grade cervical lesions were reported in 13.98% of women with hrHPV-positive ASC-US and only in 2.84% of hrHPV-negative ASC-US cases.^[2] In another study, the immediate histopathologic follow-up revealed that 7.1% of cases who were diagnosed with ASC-US had high-grade cervical lesions, including 0.6% carcinomas.^[3] In the United States, the prevalence of high-grade cervical cancer precursors in women with ASC-US ranges from 5.1% to 9%.^[8] The prevalence of high-grade cervical lesions in patients with ASC-US and positive hrHPV is 0.8% in the United Arab Emirates.^[5] Closer histopathologic follow-up of ASC-US cases, especially when the hrHPV test is positive, is crucial to predicting the malignant transformation of the cervical lesions.

In the present study, the number of cytologic follow-ups within 1 year of ASC-US diagnosis was conducted in only 32% (84/259) of the cases. Most of them regressed into NILM (73.8%) or had persistent ASC-US (17.9%), and these figures are comparable to previously published reports where the majority of ASC-US regressed spontaneously within 6 months of the first diagnosis.^[15,16] Most of the cases that regressed into normal cervical cytology were not infected with hrHPV. We found that 7/84 cases progressed into either LSIL or HSIL, and all these cases were positive for hrHPV. Those precursor lesions were more likely to progress into LSIL or HSIL if hrHPV was positive, as published before.^[15] This demonstrates that the ASC-US could be the precursor of more advanced cytologic cervical abnormalities and testing cervical lesions for hrHPV may identify those that are likely to progress.

We showed that ASC-US can progress into more advanced cervical cytologic diagnoses or contribute to the malignant transformation of cervical tissue, especially in the presence of hrHPV infection. While hrHPV infection was detected in 30% of ASC-US cases overall, it was detected in all ASC-US cases that went on to develop a more advanced cytological or histological diagnosis. This highlights the importance of hrHPV infection in disease pathogenesis and progression and speculates that using cotesting (a combination of hrHPV genotyping and Pap smear test) could be an effective strategy to identify patients at high risk of premalignant disease. This could also have an additional advantage in that it saves the patient from the inconvenience of a second visit for hrHPV testing.

The limitations of this study are the overall small number of ASC-US cases, and around 40% of them did not undergo hrHPV testing. In addition, the relatively small number of ASC-US cases who had a cervical biopsy within 6 months of diagnosis made it difficult to test for statistically significant

associations. In addition, the 1-year cytologic follow-up was not done for more than half of the patients diagnosed with ASC-US; this might be explained by patients not showing up for their follow-up appointments or going to private hospitals for follow-up tests.

SUMMARY

This is the largest and first investigation of hrHPV positivity rates, cytologic progression, and histopathologic follow-up results in women with ASC-US cytology Pap smear results in Bahrain. The findings of this study aided in providing a better understanding of the status of this cervical cytology finding in our population. The reporting rates of ASC-US in Bahrain fell within the worldwide reported range. Although most of the ASC-US cases regressed into NILM, ASC-US can progress into more advanced cervical cytologic diagnoses or contribute to the malignant transformation of cervical tissue, especially in the presence of hrHPV infection, which was positive in 30% of the ASC-US cases, and most of them were infected with the other hrHPV genotype. This emphasizes the role of cotesting (a combination of hrHPV genotyping and Pap smear test) and the importance of colposcopic evaluation of those women and the cytologic follow-up test at 1 year of diagnosis. Implementing these recommendations in the cervical cancer screening practice in Bahrain will help in having a better management plan for ASC-US women and in decreasing avoidable invasive diagnostic and therapeutic procedures.

AVAILABILITY OF DATA AND MATERIALS

All data points generated or analyzed during this study are included in this article and there are no further underlying data necessary to reproduce the results.

ABBREVIATIONS

ASC-US - Atypical squamous cells of undetermined significance
 CIN - Cervical intraepithelial neoplasia
 GCC - Gulf Cooperation Council
 HPV - Human papillomavirus
 HrHPV - High-risk human papillomavirus
 HSIL - High-grade squamous intraepithelial lesion
 LSIL - Low-grade squamous intraepithelial lesion
 NILM - Negative for intraepithelial lesion or malignancy
 PCR - Polymerase chain reaction.

NextGen CelBloking™ Kits

**Frustrated with your cell blocks?
We have a better solution!**

Nano

Nano NextGen CelBloking™

Cell block kit to process single scattered cell specimens and tissue fragments of **any** cellularity.

PATENT PENDING

Pack #1

Pack #2

Micro

Micro NextGen CelBloking™

For cellular specimens (more than 1 ml concentrated specimen with Tissuecrit more than 50%)

PATENT PENDING

Pack #2
